1 Introduction

SOL is a simple language that allows programmers to create 2D animations with ease. Programmers will have the ability to define and create objects, known as shapes, and dictate where they appear, and how they move. SOL uses point (visual dot) and Bézier Curves with three control points as the basic drawing controls provided to the programmer for defining shapes. As a lightweight object-oriented language, SOL allows for unlimited design opportunities and eases the burden of animation. In addition, SOLs simplicity saves programmers the trouble of learning complicated third-party animation tools, without sacrificing control over behavior of objects.

2 Conventions

The following conventions are followed throughout this SOL Reference Manual.

- 1. literal Fixed space font for literals such as commands, functions, keywords, and programming language structures.
- 2. variable Italics for variables, words, and concepts being defined.

The following conventions are applied while drawing and animating objects, using internal functions (see Section 8):

- 1. The origin of the drawing canvas is on the top left of the screen.
- 2. The positive X-axis goes from left to right.
- 3. The positive Y-axis goes from top to bottom.
- 4. Positive angles specify rotation in a clockwise direction.
- 5. Coordinates are specified as integer arrays of size 2, consisting of an X-coordinate followed by a Y-coordinate.
- 6. Colors are specified as integer arrays of size 3, consisting of Red, Green and Blue values in the range 0 255, where [0, 0, 0] is black and [255, 255, 255] is white.

3 Lexical Conventions

This section describes the complete lexical conventions followed for a syntactically correct SOL program, forming various parts of the language.

3.1 Comments

Comments in SOL start with character sequence /* and end at character sequence */. They may extend over multiple lines and all characters following /* are ignored until an ending */ is encountered.

3.2 Identifiers

In SOL, an identifier is a sequence of characters from the set of english alphabets, arabic numerals and underscore (_). The first character of an identifier should always be a lower case english alphabet. Identifiers are case sensitive. Identifiers cannot be any of the reserved keywords mentioned in section 3.3.

3.3 Keywords

Keywords in SOL include data types, built-in functions, and control statements, and may not be used as identifiers as they are reserved.

int	if	main	shape
float	while	setFramerate	
char	func	getFramerate	
string	construct	print	
	return	consolePrint	
		intToString	
		floatToString	
		charToString	
		render	
		wait	
		drawPoint	
		drawCurve	
		translate	
		rotate	

3.4 Integer Constants

A sequence of one or more digits representing a number in base-10, optionally preceded by a unary negation operator (-), to represent negative integers. Example: 1234

3.5 Float Constants

Similar to an integer, a float has an *integer*, a decimal point (.), and a fractional part. Both the integer and fractional part are a sequence of one or more digits. A negative float is represented by a preceding unary negation operator (-).

Example: 0.55 10.2

3.6 Character Constants

An ASCII character within single quotation marks.

Example: 'x' 'a'

3.7 Escape Sequences

The following are special characters represented by escape sequences.

Name	Escape
newline	\n
tab	\t
backslash	\\
single quote	\',
double quote	\"
ASCII NUL character	\0

3.8 String constants

A SOL string is a sequence of zero or more characters within double quotation marks.

Example: "cat"

3.9 Operators

SOL has mainly four categories of operators defined below:

3.9.1 Assignment Operator

The right associative assignment operator is denoted by the (=) symbol having a variable identifier to its left and a valid expression on its right. The assignment operator assigns the evaluated value of expression on the right to the variable on the left.

3.9.2 Unary Negation Operator

The right associative unary negation operator (-) can be used to negate the value of an arithmetic expression.

3.9.3 Arithmetic Operators

The following table describes binary arithmetic operators supported in SOL which operate on two arithmetic expressions specified before and after the operator respectively. The said expressions must both be of type

int or float. Please refer to section 5.1 for precedence and associativity rules.

Operator	Definition
+	Addition
-	Subtraction
*	Multiplication
/	Division
%	Modulo

3.9.4 Comparison Operators

The comparison operators are left associative binary operators for comparing values of operands defined as expressions. Please refer to section 5.1 for precedence and associativity rules.

Operator	Definition
==	Equality
!=	Not Equals
<	Less than
>	Greater than
<=	Less than or equals
>=	Greater than or equals

3.9.5 Logical Operators

The logical operators evaluate boolean expressions and return an integer as result: with 0 as *False* and 1 as *True*. Please refer to section 5.1 for precedence and associativity rules.

Operator	Definition
&&	AND
	OR
!	NOT

3.10 Punctuators

The following symbols are used for semantic organization in SOL:

Punctuator	Usage
{}	Used to denote a block of code. Must be present as a pair.
()	Specifies conditions for statements before the subsequent
	code, or denotes the arguments of a function. Must be
	present as a pair.
	Indicates an array. Must be present as a pair.
;	Signals the end of a line of code.
,	Used to separate arguments for a function, or elements in
	an array definition.

4 Identifier Scope

4.1 Block Scope

Identifier scope is a specific area of code wherein an identifier exists. A scope of an identifier is from its declaration until the end of the code block within which it is declared.

4.2 File Scope

Any identifier (such as a variable or a function) that is defined outside a code block has file scope i.e. it exists throughout the file.

If an identifier with file scope has the same name as an identifier with block scope, the block-scope identifier gets precedence.

5 Expressions and Operators

5.1 Precedence and Associativity

SOL expressions are evaluated with the following rules:

- 1. Expressions are evaluated from left to right as operators are left associative, unless stated otherwise.
- 2. Expressions within parenthesis take highest precedence and are evaluated prior to substituting in outer expression.

- 3. The unary negation operator (-) and logical not operator (!) are placed at the second level of precedence, above the binary, comparison and logical operators. It groups right to left as described in section 3.9.2.
- 4. The third level of precedence is taken by multiplication (*), division (/) and modulo (%) operations.
- 5. Addition (+) and subtraction (-) operations are at the fourth level of precedence.
- 6. At the fifth level of precedence are the comparison operators: <, >, <=, >=.
- 7. At sixth level of precedence are the equality comparison operators: == and !=.
- 8. The logical operators, OR (||) and AND (&&) take up the next level of precedence.
- 9. At the final level of precedence, the right associative assignment operator (=) is placed, which ensures that the expression to its right is evaluated before assigning to the left variable identifier.

5.2 Dot Accessor

To access members of a declared **shape** (further described in section 11), use the dot accessor '.' followed by the identifier name of the *member variable* or *member function*.

Example: shape_object.point1 /* This accesses the variable point1 within the object shape_object */

6 Declaring Identifers

Declarations determine how an identifier should be interpreted by the compiler. A declaration should include the identifier type and the given name.

6.1 Type Specifiers

SOL provides four type specifiers for data types:

• *int* - integer number

- float floating point number
- char a single character
- string string (ordered sequence of characters)

6.2 Declaring Variables

An identifier, also referred to as a *variable*, is declared by specifying the **primitive type** or name of the **Shape**, followed by a valid identifier, as specified in section 3.2. Variables can be declared only at the beginning of a function or at the top of the source files, as global variables, which are accessible within all subsequent function or shape definitions.

6.3 Array Declarators

An array may be formed from any of the primitive types and shapes, but each array may only contain one type of primitive or shape. At declaration, the type specifier and the size of the array must be indicated. The array size need not be specified for strings, which are character arrays. SOL supports fixed size arrays, declared at compile time i.e. a program can not allocate dynamically sized arrays at runtime. Arrays are commonly used in SOL to specify coordinates with two integers and specify drawing colors in RGB format with an array of three integers.

Example: int[2] coor; /* Array of two integers */

6.4 Function Declarators and Definition

Functions are declared with the keyword: func. This is followed by the return type of the function. If no return type is specified, then the function automatically does not return any value. Functions are given a name (a valid identifier) followed by function formal arguments. These arguments are a comma-separated list of variable declarations within parentheses. Primitives are passed into functions by value, and objects and arrays are passed by reference. This function declaration is then followed by the function definition, within curly braces; functions must always be defined immediately after they are declared.

Functions can also be defined within shape definitions in which case they are

referred as member functions of the shape. (see section 11)

Example:

```
func example(int a, int b){
    /* a function named example that takes
        two arguments, both of type int */
}
```

6.5 Constructor Declarators

Constructors are declared with the keyword: construct. Constructor definitions are similar to function definitions with three additional constraints:

- 1. Constructors are defined inside the *shape* definition
- 2. A constructor is defined with the **construct** keyword, followed by optional formal arguments, within parenthesis as a comma-separated list of variable declarations, similar to function definitions
- 3. Constructors do not have a return type specified

Example:

```
shape Point {
   int [2] coordinate;
   construct (int x, int y) {
        /* constructor definition */
        coordinate[0] = x;
        coordinate[1] = y;
   }
}
```

Please see section 11 for defining shapes in SOL and creating shape instances.

6.6 Definitions

A definition of a primitive type variable includes a value, assigned by the assignment operator '='. For defining arrays, rvalue is the sequence of array literals within square brackets. *Shapes* are objects which are initialized by calling the construct, with optional parameters (see section 11). In SOL

programs, all variables *must* be *declared* before assigning values. Example:

```
char y;  /* declarations */
float z;
int [3] w;  /* array declaration */
string s;
Triangle t;

y = 'b';  /* definitions */
z = 3.4;
w = [5, 2, 0];
s = "cats";
t = shape Triangle();  /* a triangle object */
```

7 Statements

A statement in SOL refers to a complete instruction for a SOL program. All statements are executed in order of sequence. The four types of statements are described in detail below:

7.1 Expression Statement

Expression statements are those statements that get evaluated and produce a result. This can be as simple as an assignment or a function call.

```
Example: x = 5; /* assign 5 to identifier x */
```

7.2 If Statement

An *if* statement is a conditional statement, that is specified with the **if** keyword followed by an *expression* specified within a pair of parenthesis; further followed by a block of code within curly braces. The code specified within the **if** block executes if the expression evaluates to a non-zero *integer*. Example:

```
int x;
x = 1;
```

```
if (x == 1) {
    /* This code gets executed */
}
```

7.3 While Statement

A while statement specifies the looping construct in SOL. It starts with the while keyword, followed by an expression specified within a pair of parenthesis; this is followed by a block of code within curly braces which is executed repeatedly as long as the condition in parentheses is valid. This condition is re-evaluated before each iteration and the code within while block executes if the condition evaluates to a non-zero integer.

Example:

```
int x;
x = 5;
while (x > 0) {
    /* This code gets executed 5 times */
    x = x - 1;
}
```

7.4 Return statement

The return statement stops execution of a function and returns to where the function was called originally in the code. Potentially returns a value; this value must conform with the return type specified in the function declaration. If no return type was specified, a *return* statement without any value specified is syntactically valid (but not compulsory). Example:

```
func int sum(int x, int y) {
    /* return sum of two integers */
    return x + y;
}
```

8 Internal Functions

SOL specifies a set of required/internal functions that must be defined for specific tasks such as drawing, rendering or as an entry point to the program, described below.

8.1 main

Every SOL program must contain a main function as this is the entrypoint of the program. The main function may declare and define variables or shape objects or call other functions written in the program. The main function does not take inputs as SOL programs do not depend on user input. Example:

```
func main() {
    /* Entry point for SOL programs */
    int x; /* variable declaration */
    x = 1; /* assign value */
    consolePrint("Hello World"); /* call function */
}
```

Arguments: None

8.2 setFramerate

Call setFramerate to specify frames per second to render on screen. The frame rate is specified as a *positive integer argument* and returns 0 for success and -1 to indicate failure. By default, frame rate is set to 30 frames per second for a SOL program.

Arguments: rate (int)
Return: 0 for success, -1 for failure

8.3 getFramerate

Call getFramerate to get the current number of frames rendered per second as an *integer*.

Arguments: None

Return: frames per second (int)

8.4 consolePrint

Prints a string to the console. Com monly used to print error messages.

Arguments: text (string)

8.5 round

The round function accepts a float argument and returns the value rounded to nearest integer value, rounding halfway cases away from zero instead of to the nearest integer.

<u>Argument</u>: value (float) <u>Return</u>: result (float)

8.6 Trigonometric functions

SOL provides two basic trignometric functions, sine and cosine which can be used to easily calculate coordinates for displaying objectes or other arithmetic calculations in SOL programs.

8.6.1 sine

The sine function accepts an argument of type float, representing an *angle* in degrees and returns the *sine* value.

 $\frac{\text{Arguments:}}{\text{Return:}}$ sine value (float)

8.6.2 cosine

The cosine function accepts an argument of type float, representing an *angle* in degrees and returns the *cosine* value.

Arguments: angle (float)
Return: cosine value (float)

8.7 Type Conversion Functions

SOL provides following type conversion functions for converting expressions of a given type to an expression of another type.

8.7.1 int ToString

Accepts an expression (src) of type int as the argument and returns the string representation of evaluated result.

Argument: src (int)

Return: value of type string

8.7.2 float ToString

Accepts an expression (src) of type float as the argument and returns the string representation of evaluated result.

<u>Argument</u>: src (float)

Return: value of type string

8.7.3 charToString

Accepts an expression (src) of type char as the argument and returns the string representation of evaluated result.

Argument: src (char)

Return: value of type string

8.7.4 intToFloat

Accepts an expression (src) of type int as the argument and returns the float representation of evaluated result.

Argument: src (int)

Return: value of type float

8.7.5 float ToInt

Accepts an expression (src) of type float as the argument and returns the int representation of evaluated result.

Argument: src (float)
Return: value of type int

9 Drawing Functions

The following set of functions are also a category of internal/required functions, which describe the drawing aspects for **shape** objects defined in a SOL

program.

9.1 drawCurve

drawCurve is one of the basic internal functions; it is used to draw a Bézier curve. SOL aims to define all possible shapes as a collection of Bézier curves. The function arguments in order are, the *three control points* for the curve, a *step size* to control smoothness of the curve, and the *color* of curve (in RGB format).

Arguments: pt1 (int[2]), pt2 (int[2]), pt3 (int[2]), steps(int), color (int[3])

9.2 drawPoint

Draws a point at a specified coordinate in the specified color.

Arguments: pt (int[2]), color (int[3])

$9.3 \quad print$

Displays horizontal text on the render screen at the coordinates specified by the user, in the specified color.

<u>Arguments</u>: pt (int[2]), text (string), color (int[3])

$9.4 \quad draw$

For every shape definition, there must be a draw function defined by the programmer. The draw function does not accept any input arguments and is called internally to display the object on screen. The drawCurve, drawPoint and print functions calls can be used within the draw definition to describe the actual drawing of an object.

At runtime draw functions of all objects instantiated in the main function are called, to render the final scene.

10 Animation Functions

The following functions are used to animate the objects drawn in a SOL program.

10.1 translate

Displaces a **shape** across a straight path by specifying a two-element array of relative displacements - the first element is the displacement in pixels along the horizontal axis and the second element along the vertical axis - over a specified time period (in seconds).

Arguments: displace (int[2]), time (int)

10.2 rotate

Rotates the position of a shape around a specified axis point by a specified angle (in degrees), over a time period (in seconds).

Arguments: axis (int[2]), angle (float), time (float)

10.3 render

Specifies the set of motions to be animated. This code-block can be defined for shapes that need to move, or can be left undefined for static shapes. Within this block, various rotate and translate calls can be made to move the shape. This must be specified in the main function.

11 Classes

SOL follows an object-oriented paradigm for defining objects (drawn shapes) which can be further animated using the animation functions described in Section 10.

11.1 shape

Similar to a class in C++; a *shape* defines a particular 2-D shape as part of the drawing on screen. The name of a *shape* must always start with an uppercase english alphabet.

11.1.1 Shape definition

A *shape* definition starts with the **shape** keyword, followed by the *shape* name,(Example: Triangle) and the definition within curly braces ($\{\}$) code

block. Shape definitions may optionally contain member variables.

Every *shape* must define a *constructor* using **construct** keyword and draw function. The **construct** definition can optionally have *formal arguments* as input parameters. The draw function does not accept any arguments and its definition can have multiple drawPoint, drawCurve and print function calls to describe the screen display of the *shape* object.

It is possible to define functions in a shape definition. The member functions are defined with the same rules as specified in section 6.4.

When member variables are accessed within a member function, it is implied that the member variables belong to the current object that calls the function. If a member variable or global variable name is same as that of a local variable or formal argument in function definition, then the local variable or formal argument overshadows the other conflicting variable.

Example:

```
shape Triangle {
    int[2] a; /* Corners of a triangle */
    int[2] b;
    int[2] c;
               /* mid points of lines*/
    int[2] p;
    int[2] q;
    int[2] r;
    construct (int [2]x, int [2]y, int [2]z) {
        a = x;
        b = y;
        c = z;
        findCenter(p, a, b);
        findCenter(q, b, c);
        findCenter(r, a, c)
    }
    /* internal draw function definition */
```

11.1.2 Creating Shape Instances

Actual instances for a *shape* definition can be created, which represent the actual shapes rendered on the screen.

To instantiate an object for a shape, we first declare a variable of defined *shape* (say Triangle) and then instantiate it by calling the *constructor*. Example:

```
func main() {
    /* declare variable of shape Triangle */
    Triangle t;

    /* instantiate a triangle */
    t = shape Triangle([100,100], [200,100],
        [150,200]);
}
```
